Explainable Data

What data was used to train the model and why?

Explainable Predictions

What features and weights were used for this particular prediction?

Explainable Algorithms

What are the individual layers and the thresholds used for a prediction?

WHY TRACEABILITY AND EXPLAINABILITY OF AI/ML MODELS IN MEASUREMENT AND TESTING TECHNOLOGY ARE MORE IMPORTANT THAN ACCURACY AND PRECISION

Conclusions and Outlook

Issues and pitfalls
Lessons learned

BASICS

- **Data-driven Methods for**
 - Structural Health Monitoring
 - Damage Diagnostics
 - Material Testing
- **Data-driven Methods in**
 - Measurement - Sensors
 - Signal Processing
 - Aggregation
 - Transformation
 - Fusion
 - Interpretation (Prediction)
 - Generation

BASICS

Accuracy versa Precision

- Strong. Accuracy: Close to expectation value (ground truth)
- Weak. Precision: Low variance

Explainability versa Traceability or Tracktability

- Strong. Explainability: An inductive model relationship between x and y based on knowledge
- Weak. Traceability: Which input contributes to output?

Generalization: Specific or more general?

- Interpolation versa Extrapolation

We have an opposite relationship between model accuracy and model explainability! And what's about model generalization?

BASICS

Interpolation versa Extrapolation: Prediction Errors?

Models

- Trees: I/E NA (partly by regression trees)
- Functions and Functional Graphs (SVM, ANN, CNN, ..)
- Training = Definition from Data \leftrightarrow Def. Parameter Space

Interpolation

- Input values between training points but inside parameter space

Extrapolation

- Input (and output) values outside the parameter space

Interpolation should be possible with all functional models, extrapolation fails commonly! Generalization provides interpolation (degree 1) and extrapolation (degree 2). A specialized model will provide neither nor.

BASICS

Monitoring / Observation

- Interpolation: Test with sample set not included in training (classical validation) but same parameters ϕ
- Extrapolation: Different sample distributions ϕ for test and training data
- Training Data versa Test Data: Accuracy, Precision, ...

Robustness

- What is the output if the input is outside of the definition parameter space or non-sense data?
- Noise sensitivity?

Training error low, test error high: Specialized Model ▶ Nice to have, but useless!

Training and test error low: Interpolating Model ▶ Degree 1 of Generalization

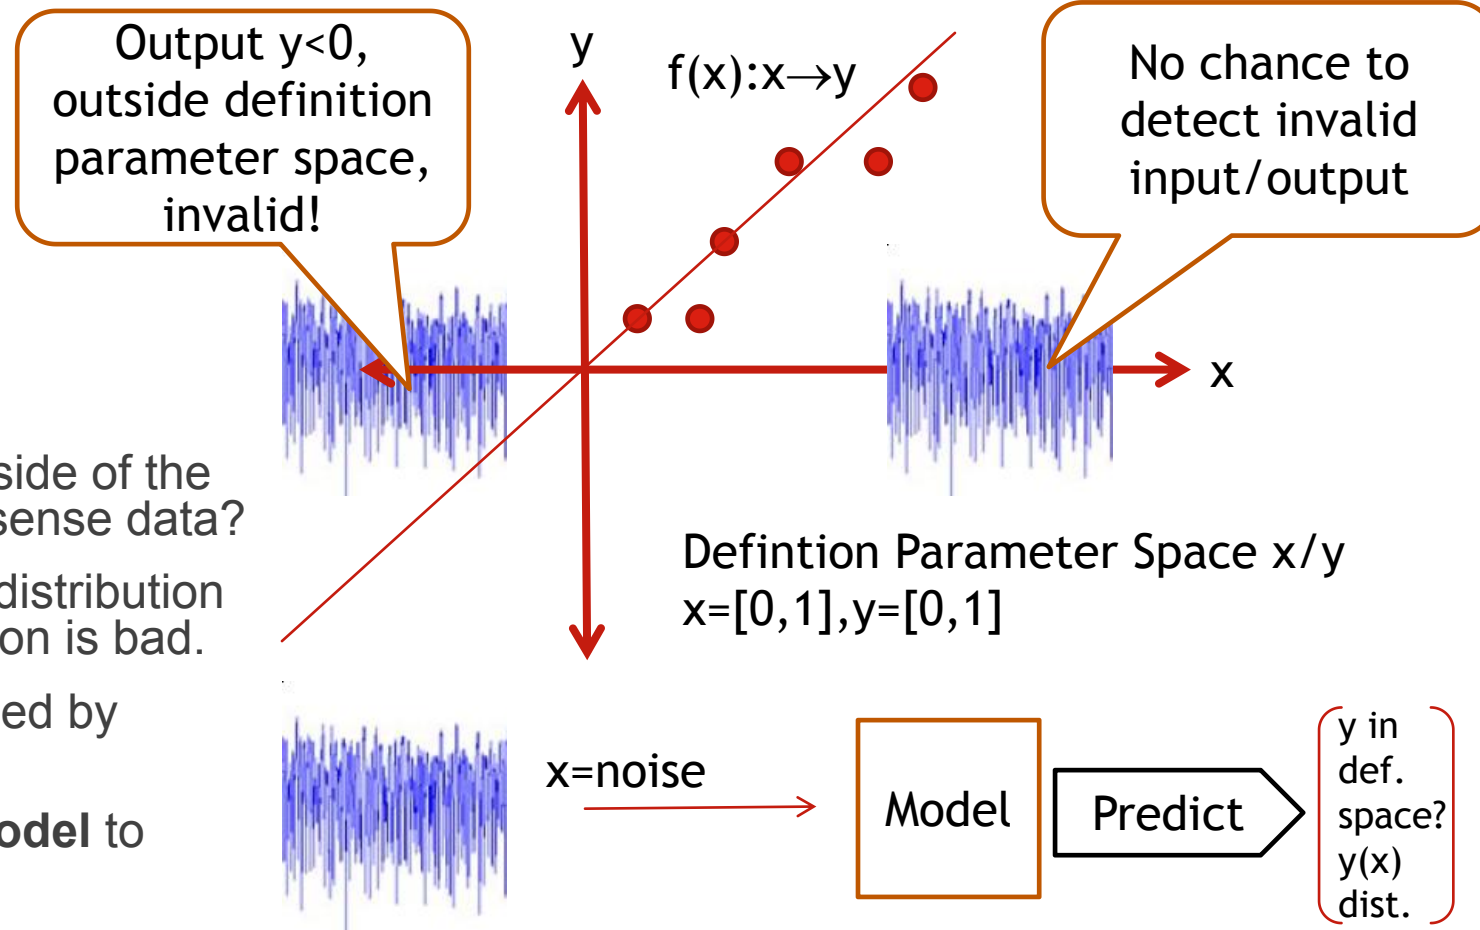

Different sample distributions covering different parameter spaces:

Extrapolation Test, low error outside training distribution ▶ Degree 2 of Generalization

BASICS

Robustness

- What is the output if the input is outside of the definition parameter space or non-sense data?
- Noise sensitivity? Make a $y(\text{noise})$ distribution test - high variant $y(\text{noise})$ distribution is bad.
- Can we detect **invalid output** caused by **invalid input**?
- Do we need a separate **scoring model** to classify input data validity? Or the „noise“ class as additional output?

With simple models we can maybe recognize and detect invalid input and invalid output. With any complex, highly non-linear, multi-variate and deep (nested) models this is mostly impossible!

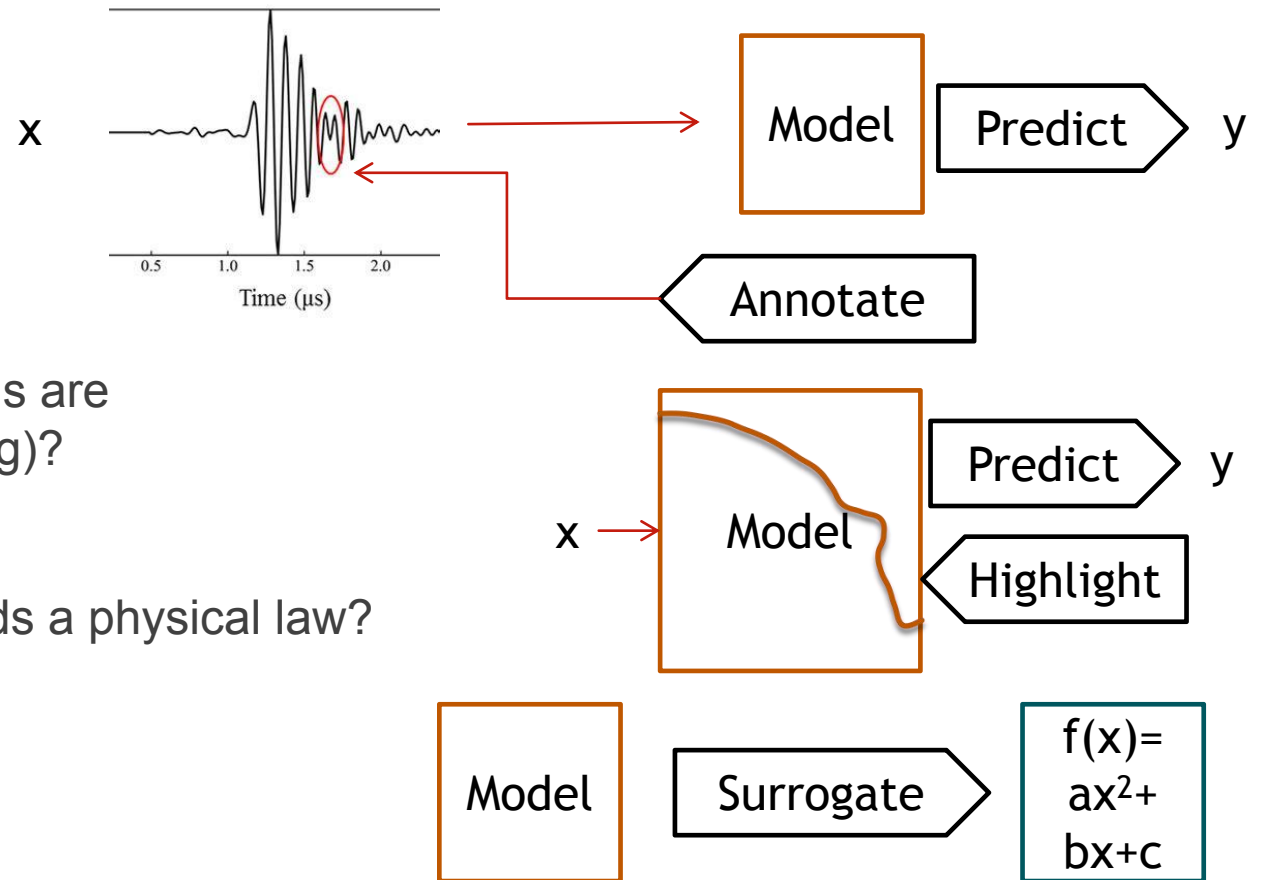

BASICS

Traceability

- Which part of input is relevant?
- Which functional terms or paths in graphs are contributing to output (or decision making)?

Explainability

- Anything learned? Generalization towards a physical law?
- Analytical explanations $x \rightarrow y$?
- Surrogate Modeling
- Explainable Models (e.g. XANN)

The most important methodology: Explain the model behavior or extraxt knowledge from a data-driven model. Induction is better than Deduction.

PREDICTION VERSA GENERATION

Signal Data Generation: Output is Signal

- Model-driven or random Augmentation from real measured data (linear independent data?), additive and multiplicative noise, super-position (real-synthetic)
- Model-based or Model-driven Simulation Methods (Physics-driven but Reality gap!)
- Model-free Random-process Generative Models (data-driven), e.g. Generative Adversarial Networks or Variational Autoencode Models
- Model-free (?) or Model-driven Parameterizable Generative Models (data-driven)

Motivation: Lack of parameter variance and sparse parameter space coverage of experimental data.

The most important question of signal data generation: Produces the generator what we want - is it physically correct, and is the parameter space broadly covered?

EXAMPLE 1: USELESS DATA-DRIVEN MODEL

Ultrasonic High-frequency Pulse-Echo Measurements for Porosity Detection in Die-casted Aluminum Plates

Input

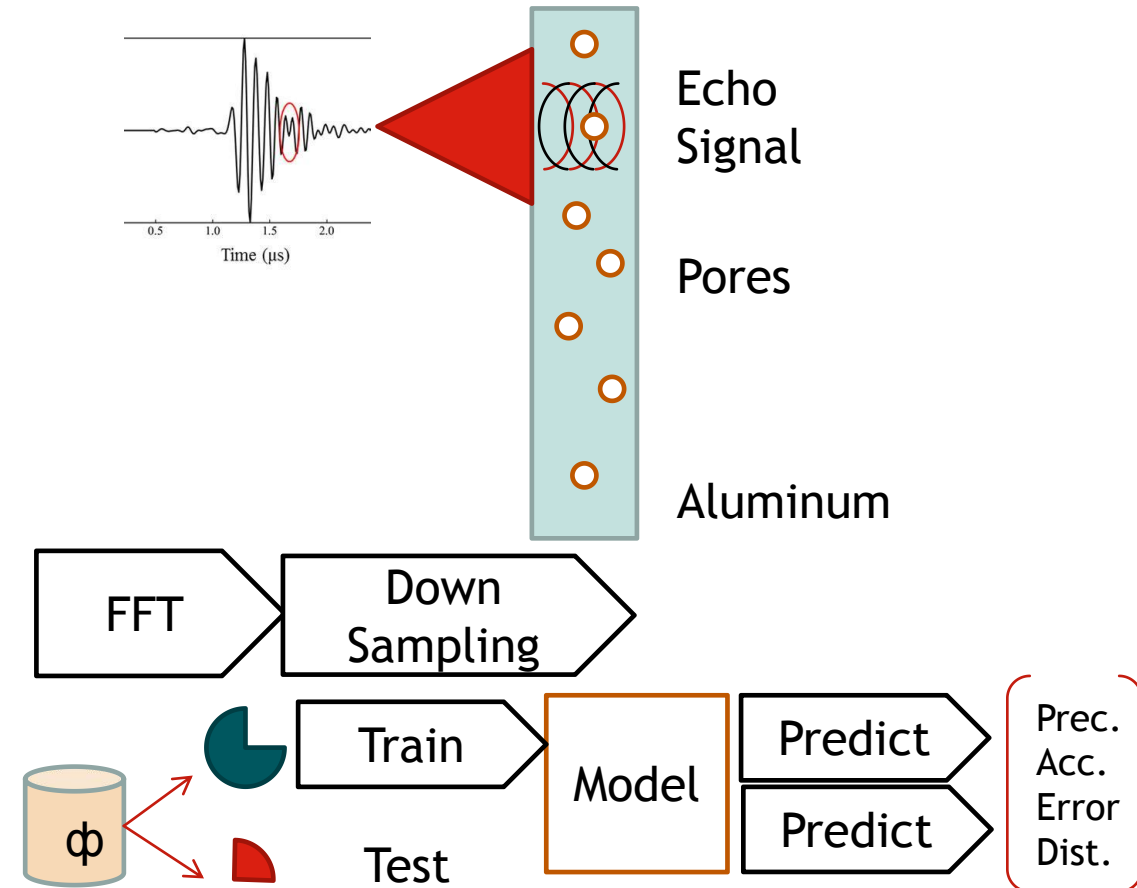

- Time-resolved US signal (stimuls: bipolar pulse, broad frequency spectrum) , 50 specimens, 3 measuring locations
- Transducer: Dual-piezo-crystal, 5 MHz, 10 mm Dia.
- Material: Aluminum alloys (primary, secodary 58/89%)

Features

- Frequency spectrum of response signal (FFT)
- Assumption: Attenuation is frequency dependent and frequency spectrum is depending on pores (size, density)

Output

- Pore grade classification (A,B,C,D)
- Simple ANN (two layers [10,5], sigmoid activation function softmax output layer)

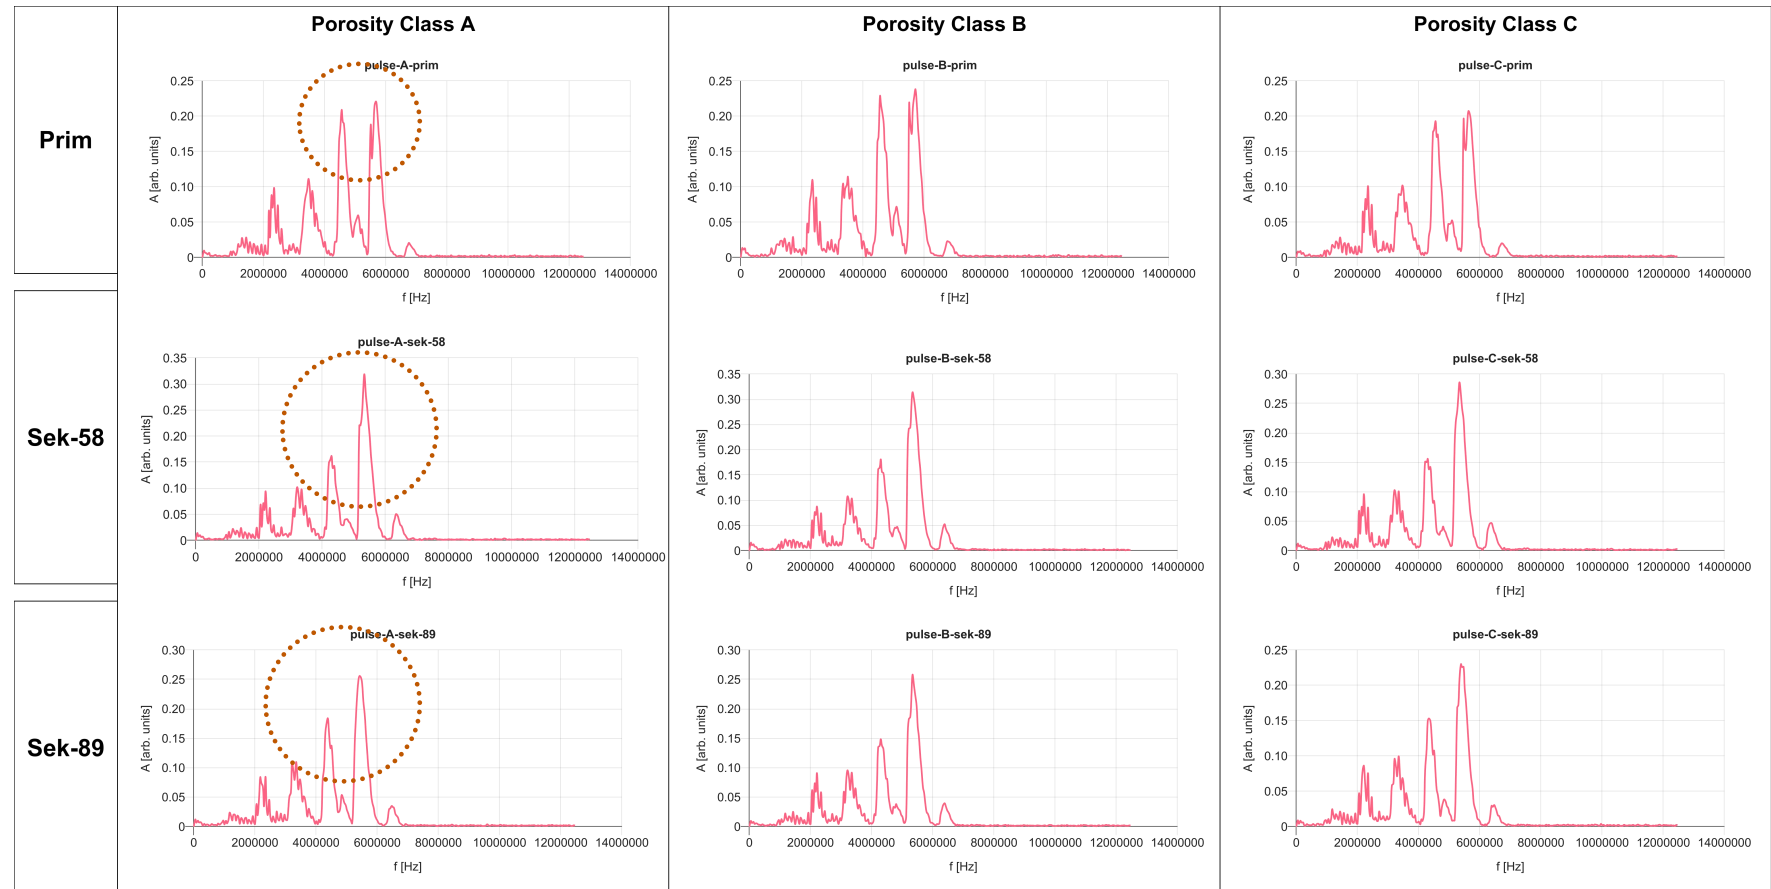

EXAMPLE 1: USELESS DATA-DRIVEN MODEL

Ultrasonic High-frequency Pulse-Echo Measurements for Porosity Detection in Die-casted Aluminum Plates

*No porosity
class
correlation
visible.
Hidden?*

*Classification
of alloy class is
directly visible!
Strong feature
correlation*

EXAMPLE 1: USELESS DATA-DRIVEN MODEL

Ultrasonic High-frequency Pulse-Echo Measurements for Porosity Detection in Die-casted Aluminum Plates

Data

- ϕ : 50 specimen x 3 positions x 5 augmentation (multiplicative normal distributed noise 10%), mixed 3 alloys
- Training/Test split: 80/20% (random)

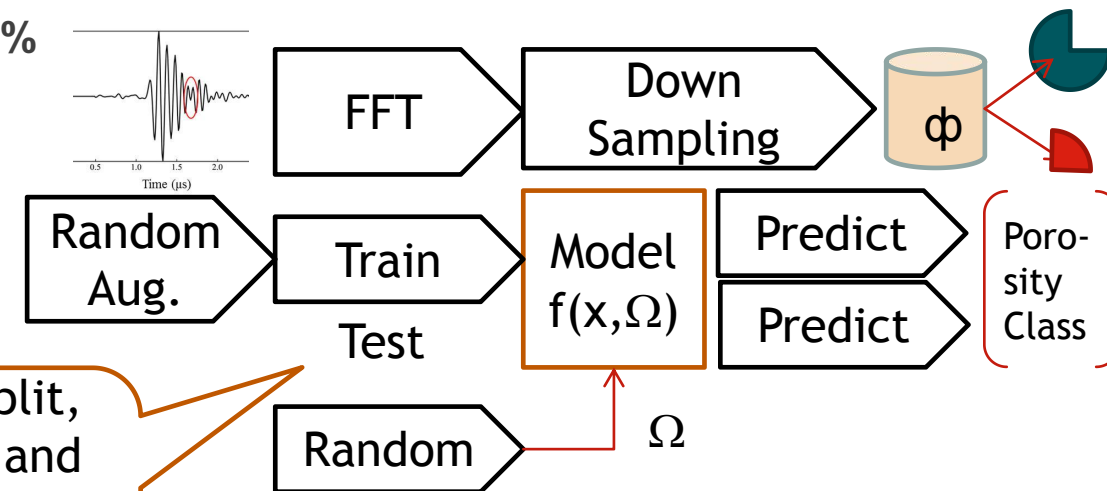

Results

- Training of ANN (adam optimizer) with augmented data: Smooth and convergent!
- Classification error: **Training Data=0%..3% (!), Test=40%±20%**

Explainability

- Large Training/Test error ratio: **Specialized Model!** No I/E
- Very small/weak input features were amplified resulting in a practical unusable, unpredictable and instable model
- **Unknown functional x-y relation**

Interpolation (I)/
Extrapolation (E)
Tests not possible

Random data split,
augmentation, and
model training was
repeated N times
(Statistics)

EXAMPLE 2: GENERATIVE MODEL

Random-process and Data-driven Generative Model for Guided Ultrasonic Wave Data

Signals

- Time-resolved US signal (stimulus: gaussian-masked sine pulse, narrow frequency spectrum)
- Assumed measuring set-up: On sender transducer, one receiver transducer, single and straight path
- Material: Solid (e.g., Aluminum), Damage: Air, e.g. a circular hole

Simulation and Ground-truth (GT) Data

- Parameter space is limited - simulation using visco-elastic wave equation is used
- A large set of data can be generated with exact labelling (GT)

Generative Model

- Generative Adversarial Network (GAN)
- Input: Random vector, Output: GUW signal, Training: GUW signals from simulation

$$\phi = \{f_{\text{wave}}, \text{dim.}, \text{pos}_{\text{dam}}, \text{size}_{\text{dam}}, T, \dots\}$$

EXAMPLE 2: GENERATIVE MODEL

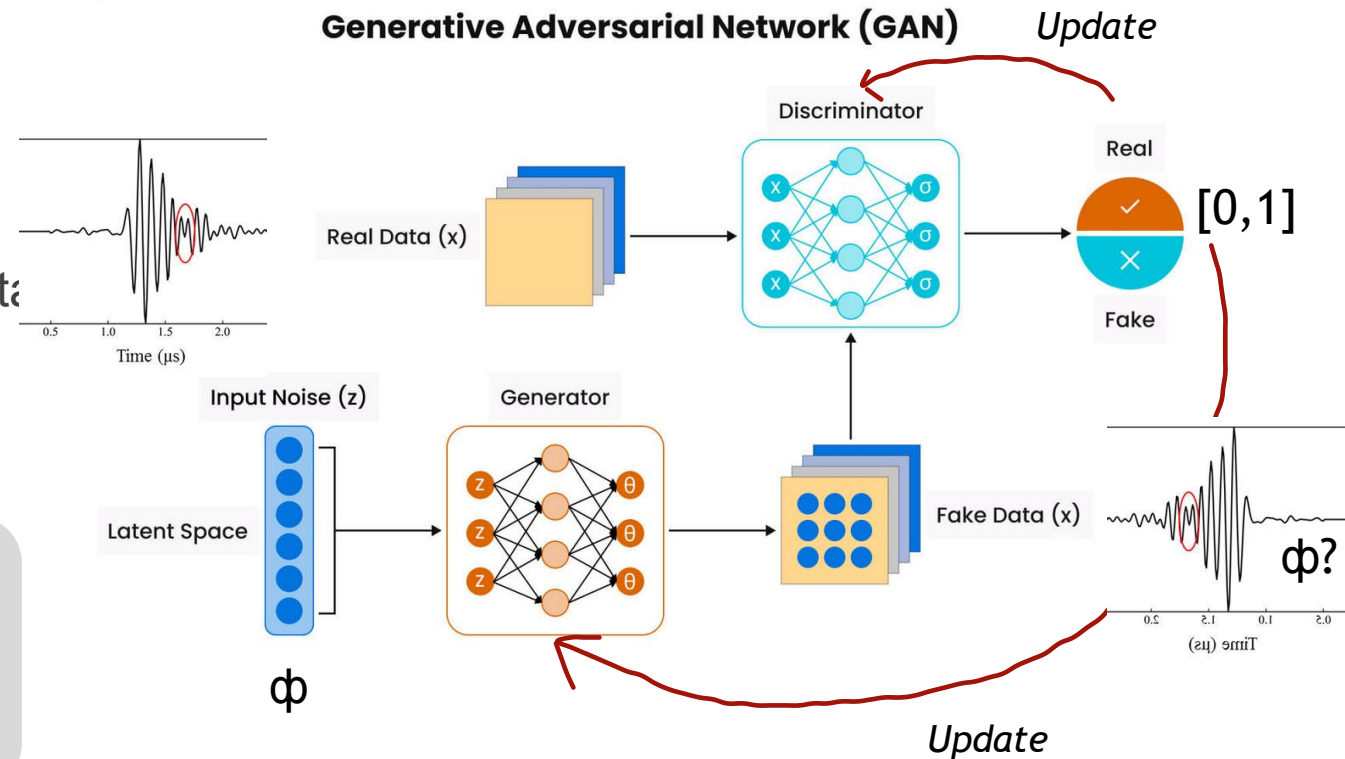

Random-process and Data-driven Generative Model for Guided Ultrasonic Wave Data

Generative Adversarial Network Model

- Generator
- Discriminator (only Training)
- The generator never sees the original data
- Feedback only from discriminator which predicts a fake score $[0,1]$

How can we evaluate the signal generator quality?
Physical correctness? Covered
Generator parameter space?

EXAMPLE 2: PARAMETER PREDICTOR MODEL

Random-process and Data-driven Generative Model for Guided Ultrasonic Wave Data

Parameter Predictor Model

- Input: GUW signal (real/simu./synth.)
- Output: Parameter vector
- Here: Damage position $\mathbf{p}_{\text{dam}}=(x,y)$, trained with simulation data (GT)
- Interpolation and Extrapolation required

Use another data-driven predictor model for the data parameter space!
Good idea? How good is the predictor?
Can we trust the model?

EXAMPLE 2: PARAMETER PREDICTOR MODEL

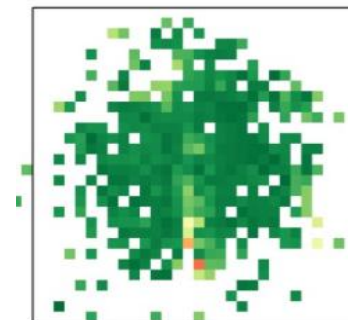

Random-process and Data-driven Generative Model for Guided Ultrasonic Wave Data

Parameter Predictor Model: IE Test

- Two sample sets (ϕ is damage location): Normal (N) and uniform (U) random distribution of damage location (x, y)
- Training with normal distributed data (80%), Test with uniform distributed data (100%)

Regr. Error Training Data (N) Test Data (N)

Test Data (U)

It seems the model is I and partly E capable, at least we can hope!

EXAMPLE 2: PARAMETER PREDICTOR MODEL

Random-process and Data-driven Generative Model for Guided Ultrasonic Wave Data

Parameter Predictor Model: IO Analysis

- Identify major input elements / regions contributing to the output (strong feature analysis), Input: signal s , Output: location coordinates (x,y)

- Gradient is a measure of activation:

$$\frac{\partial x}{\partial s_i} \approx \frac{\Delta x}{\Delta s_i}, \quad \frac{\partial y}{\partial s_i} \approx \frac{\Delta y}{\Delta s_i}$$

If the prediction / regression error is low then stimulus signal regions can be identified. If the error is high, no clear correlation is visible!

Feature
Selector

Model

Predict

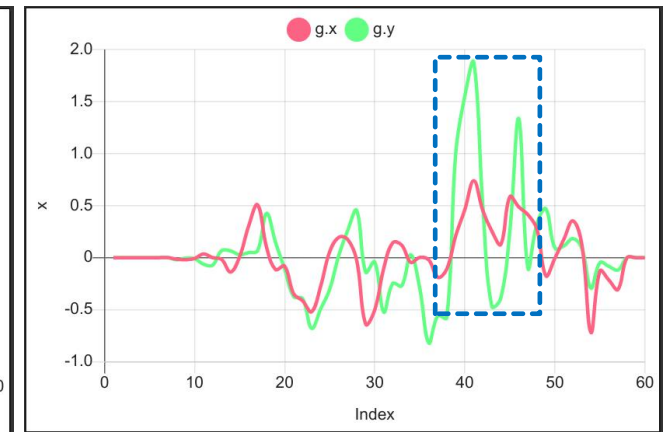

$\begin{pmatrix} x \\ y \\ \phi \end{pmatrix}$

Ground Truth	$x=352$	$y=307$
Predicted	$x=226$ (-25%)	$y=308$ (0.3%)

(CNN Model)

Signal

Gradients

EXAMPLE 2: SCORER MODEL

Random-process and Data-driven Generative Model for Guided Ultrasonic Wave Data

Parameter Predictor Model: Noise Test

- Invalid and noise data test: Feed model with pure random noise and random sine waves.
- Train an additional scorer model that tests the input signal data for validity.

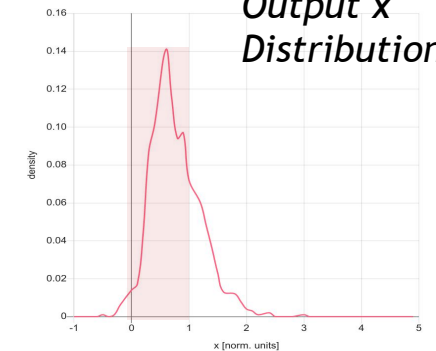

Random Sine Waves

Predict

Output x Distribution

Output y Distribution

What happens if the predictor gets noise or random data? Make a test... The predictor model outputs a broad parameter range..

EXAMPLE 2: SCORER MODEL

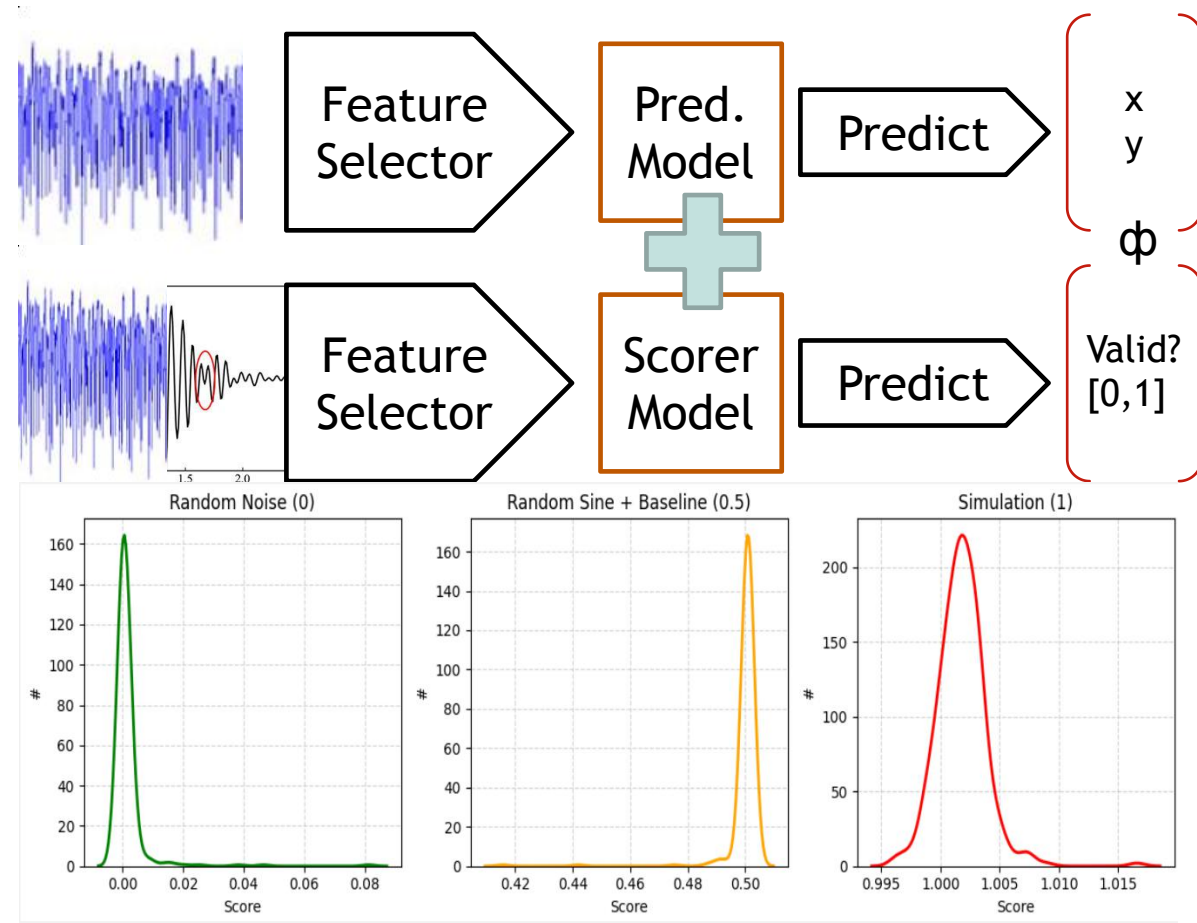

Random-process and Data-driven Generative Model for Guided Ultrasonic Wave Data

Parameter Predictor Model: Noise Test

- Invalid and noise data test: Feed model with pure random noise and random sine waves.
- Train an additional scorer model that tests the input signal data for validity.
- Hierarchical model: 1. Scorer 2. Predictor

What happens if the predictor gets noise or random data? Make a test... The predictor model outputs a broad parameter range. A scorer is required.

Noise	Random Sine Waves	GUW
0	0.3 / 0.5 (+ GUW)	1.0

CONCLUSIONS

Generalization

- Degree 1: Model can be used for Interpolation w/o large deviations within defined parameter Space
- Degree 2: Model can be used outside (trained) parameter space w/o large deviation
- Degree 3: The model is stable against noise and invalid data
- If we want to test and evaluate generative models (random process) we need degree 3!

Traceability

- Effect of input on model activation (paths inside a model) / Activation paths
- Which part or region of model input is relevant for a specific output?
- Model behavior with invalid or pure noise data, model selection

Explainability

- Do we have learned something from the data-driven model? Induction versa deduction?
- Why is the model giving a specific output for a specific input?
- Surrogate models can help to reduce a complex model to simplified and explainable well known functional laws
- Can we solve the inverse problem with a specific model?
- Can we explain generative models?
